### Citation:

Wang D, Dong D, Nie P and Wang C  
(2018) Factor Structure of the Chinese  
Version of the Parent Adult-Child  
Relationship Questionnaire.  
Front. Psychol. 9:315.  
doi: 10.3389/fpsyg.2018.00315

The PACQ consists of 26 items: 13 items measure mother and adult-child relationships, and 13 items measure father and adult-child relationships. The questionnaire section for mother and adult-child relationship assesses two factors (responsibility and regard), and the section for father-adult relationship assesses three factors (responsibility, regard, and control). Responsibility plays an important role in family loyalty and filial maturity, and is an important determinant for parent adult-child relationships. Responsibility is considered “support banks” among family members over the course of a lifetime (Schwarz et al., 2005). Regard refers to parents and children respect each other in a fair and consistent way, and with mutual respect, which involves sincere communication and support. In Pakistan, regard seems to be the leading factor for relationship quality of adolescents with their parents (Saeed and Hanif, 2014). Control is another important factor for parent-child relationships. Control has been described as an enduring emotional tie to a caregiver, particular for the father tie to their children. Studies indicated the PACQ is a reliable measure of relationships between adult-children and their parents (Pitzer et al., 2011).

Studies found other factors including age, gender, social economic status, and subcultural background (e.g., American Caucasian and American African; urban and rural in China) of adult-children may affect the relationship between adult-children and their parents (Julian et al., 1994; Bonsang, 2007; Cherlin, 2010; Babore et al., 2017; Li and Carter, 2017). Compared to western culture, there may be also different traditional connotations in the relationship between parents and children under Chinese cultural context. For example, in the west, most elderly tend to be more independent and live their own life, while in China, people mostly prefer living with their adult-children and depend on their offspring taking care of them (Bonsang, 2007; Li and Carter, 2017). Chinese culture is greatly influenced by Confucianism and is seen as a “culture of family” (Lin, 2006). Namely, it is a collectivistic culture rather than individualistic, as is Western culture. Traditionally, the Chinese are known for their strong family bonds. The concept of “filial piety” in Confucian philosophy, which is the respect for one’s parents and elders, is seen as the foundation of family bonds and considered to be the soul of traditional Chinese culture. According to this concept, Chinese parents normally feel more sense of obligation to raise and provide an education for their children, and children in turn have the duty to support their parents. In other word, parents and children in China are attached tighter to each other due to culture environment.

Previous studies which focused on the parent-child relationship have some limitations (Kaufman and Uhlenberg, 1998; Ikkin et al., 1999; Lang and Schütze, 2002; Lüscher, 2003; Trommsdorff, 2006). Previous studies focused only on young children and few studies have examined the relationships between parents and their adult-children. While one study did focus on this parent adult-child relationship, the sample was from metropolitan areas of Mainland China, such as Beijing, and rural areas have been overlooked (Lin, 2006). The distinction between rural participants and urban participants is based on *hukou* (the official Chinese household registration, in which rural participants have the agricultural *hukou* while urban

participants have the non-agricultural *hukou*) (Wang et al., 2017

**TABLE 1** | Descriptive statistics of participants' background variables.

Participants	Total ( <i>N</i> = 454)	Gender		Randomly grouped		<i>t</i>
		Female ( <i>n</i> = 327)	Male ( <i>n</i> = 127)	Group 1 ( <i>n</i> = 223)	Group 2 ( <i>n</i> = 23)	
AGE						
M±SD range	22.98 ± 7.04 (18–48)	22.04 ± 5.66 (18–48)	25.47 ± 9.40 (18–48)	23.07 ± 6.93 (18–48)	22.89 ± 7.16 (18–48)	0.28
YEARS OF EDUCATION						
M±SD range	14.65 ± 1.87 (5–19)	14.84 ± 1.44 (5–19)	14.16 ± 2.61 (5–19)	14.75 ± 1.70 (5–19)	14.16 ± 2.61 (5–19)	1.16
hukou						$\chi^2$
Non-agricultural	30.4%	29.1%	33.9%	29.1%	31.6%	0.57
Agricultural	69.6%	70.9%	66.1%	70.9%	68.4%	
GENDER						
Female	72.0%	—	—	72.2%	71.9%	0.94
Male	28.0%	—	—	27.8%	28.1%	

Gender, male = 0, female = 1; hukou, non-agricultural = 0, agricultural = 1.

**TABLE 2** | PACQ for parent adult-children relationship.

Adult-children participants	PACQ for father	PACQ for mother
Adult man (son)	Father-son relationship	Mother-son relationship
Adult woman (daughter)	Father-daughter relationship	Mother-daughter relationship

divided randomly into two subgroups (group 1 and group 2). Exploratory factor analysis (EFA) was performed for group 1, and confirmatory factor analysis (CFA) was performed for group 2. In the group 1, to identify the number of reserved components, Cattell's

shown by Peisah et al. (1999); the study reported for the mother's section, Cronbach's coefficient was 0.87 for regard and 0.82 for responsibility, and for the father's section, Cronbach's coefficient was 0.86 for regard, 0.74 for responsibility, and 0.87 for control.

The PACQ was translated into Chinese with a Chinese graduate student who majored in English, and fidelity was ensured through back translation with a native English speakers. Discrepancies were discussed until an agreement was reached between the authors, English major graduate student and native English speaker. This version was then refined, using well-known words and easy grammar to ensure that questionnaire items could be easily understood by respondents who come from development education level.

## Statistical Analysis

Responses to all items were subjected to principal component factor analysis. SPSS 22.0 (Chicago, IL, USA) and MPLUS 7 (Los Angeles, CA, USA) were used for analysis.

Data analysis included the calculation of Cronbach's  $\alpha$  for each item and the identification of psychometrically weak items. Partial eta squared was used as an estimate of effect size when interpreting multivariate analysis of variance (MANOVA) results. A principal factor analysis and Pearson correlation coefficients between subscale scores were also conducted. Cross-validation analyses were carried out since participants were

1704(s)-0.056751625.327602(n)03dtttsc33-285.506(t)-0.0.13

of the PACQ for fathers, Horn (1965) recommended the Cattell's scree test with a PA to retain only those factors whose eigenvalues are greater than those of the random data (see **Figure 1**). There was a clear discontinuity in the eigenvalues between the third and the fourth factors in the scree plot, and only the first three whose eigenvalues are greater than the random data. Therefore, we chose the three-factor solution. The three-factor solution accounted for 67.90% of the variance in the PACQ for fathers. These three factors consisted of control, regard, and responsibility. The control factor accounted for 31.44% of the variance (eigenvalue: 4.09), the regard factor accounted for 27.38% of the variance (eigenvalue: 3.56), and the responsibility factor accounted for 9.07% of the variance (eigenvalue: 1.18). These results are similar to those of the original English version (Peisah et al., 1999).

As shown in **Table 1**, most of the item scores had loadings on their expected theoretical parent adult-child relationship for fathers, with loading values  $>0.50$ , except for item 6 (responsibility). Item 6 positively loaded on responsibility with a loading value of 0.47, and on regard with a loading value of 0.77. The factor loadings for the items contributed to these factors for sons and daughters combined, as well as the factor loadings derived separately for sons and daughters (**Table 1**). The results of item loadings were similar for sons and daughters. The loading value of item 6 was  $<0.50$  for the paternal relationships with sons and daughters, and positively loaded on responsibility for paternal relationships with sons and daughters, with a loading value of 0.49 and 0.38, and on regard with a loading value of 0.62 and 0.68.

Regarding the Chinese version of the PACQ for mothers, a plot of the first 13 eigenvalues is presented in **Figure 2**. There was a clear discontinuity in the eigenvalues between the third and the fourth factors. The Cattell's scree test with PA indicated a three-factor solution, which accounted for 58.04% of the variance in the PACQ results for mothers. These three factors were regard, responsibility, and attachment. The results for the regard and

responsibility factors are similar to those of the original English version of the PACQ for mothers (Peisah et al., 1999). However, the responsibility factor was separated into two factors, namely, responsibility (items 2, 3, and 10) and anonymous factor (items 5, 7, 8, 11, and 13). From the perspective of Chinese culture, the meaning of the items (e.g., "my mother relies on me too much") in the anonymous factor was more about the emotional dependence of the mother on the adult child, which is very close to the attachment (Kerns and Brumariu, 2014). So, this additional factor termed "attachment." The regard factor accounted for 34.09% of the variance (eigenvalue: 4.43), the responsibility factor accounted for 16.11% of the variance (eigenvalue: 2.09), and the attachment factor accounted for 7.84% of the variance (eigenvalue: 1.08). As shown in **Table 1**, most of the item scores had loadings on their expected theoretical parent adult-child relationship for mothers, with loading values of  $>0.50$ . The factor loadings for the items contributing to these factors for sons and daughters were combined, as well as the factor loadings derived separately for sons and daughters (**Table 1**). The results showed that item loadings were similar for sons and daughters. The loading value of all items were  $>0.50$  for the paternal relationships with daughters, while the loading value of item 5 and item 7 (attachment) were  $<0.50$  for the paternal relationships with sons. The item 5 not only loaded on attachment with a loading value 0.48, but also on regard with a loading value  $-0.49$ . And item 7 not only loaded on attachment with a loading value 0.49, but also on responsibility with a loading value 0.37.

## Confirmatory Factor Analysis of the PACQ

Based on the CFA results of the group 2, separate CFA were performed for the father and mother sections of the Chinese version. Regarding the Chinese version of the PACQ for fathers, we first tested the original three-factor model (Model I). Because item 6 was positively loaded on responsibility with a loading value of 0.47, and on regard with a loading value of 0.77 and a loading value  $>0.50$ , item 6 was re-categorized from a responsibility factor to a regard factor. Then, we tested the revised three-factor model (Model II). Furthermore, the modification model indices for the three-factor model indicated that responsibility and regard factor may have been cross-loadings for item 6. Model misfit could be a result of failing to specify item cross-loadings (Marsh et al., 2010). Therefore, we freed freeing paths the responsibility item 6 and the regard factor (Model III). Regarding the results of the Chinese version of the PACQ for mothers, we first tested the original two-factor (regard and responsibility) model (Model IV). Second, we tested the revised three-factor (regard, responsibility, and attachment) model (Model V). Finally, we tested a hierarchical model assuming the unidimensionality of the measure (i.e., PACQ for father original three-factor and PACQ for mother original two-factor) (Model VI).

The results of the PACQ for father indicated that the Model II fit the data considerably better than the Model I ( $\Delta\text{CFI} = 0.038$  and  $\Delta\text{TLI} = 0.047$ ; **Table 1**). Although the fitting index in Model III was higher than the Model II, it was not significant ( $\Delta\text{CFI} = 0.006$  and  $\Delta\text{TLI} = 0.008$ ). Therefore, the Model II was more suitable for analyzing father and adult-child relationship

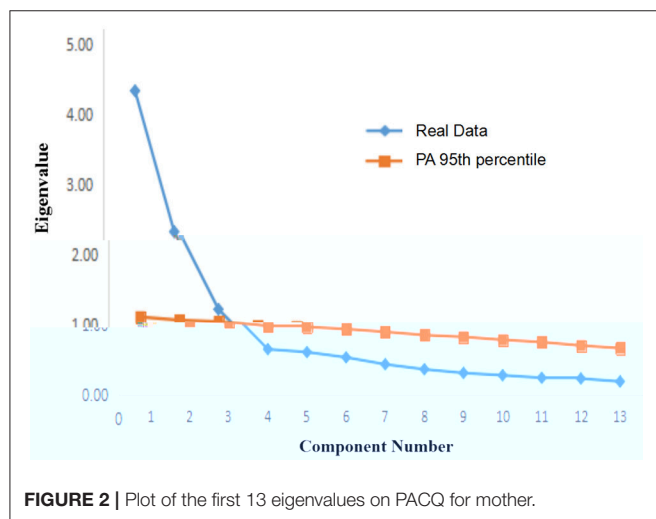

**FIGURE 1 |** Plot of the first 13 eigenvalues on PACQ for father.

**TABLE 3 |** Principal Factor analysis of the PACQ for father.

Group 1 (n = 223)	Factor loading								
	All			Sons			Daughters		
FACTOR 1: CONTROL									
1. If I don't do things my father's way he will nag me.	0.91	−0.01	0.33	0.94	0.07	0.33	0.85	−0.10	0.31
4. I feel that my father tries to manipulate me.	0.91	−0.01	0.33	0.94	0.07	0.33	0.85	−0.10	0.31
7. My father tries to dominate me.	0.79	−0.01	0.17	0.86	0.1	0.27	0.84	−0.01	−0.02
8. I feel that my father makes too many demands on me.	0.77	0.04	0.02	0.79	−0.07	0.20	0.85	0.10	−0.22
11. I don't discuss much with my father because I'm afraid of being criticized.	0.70	0.01	0.04	0.51	−0.39	−0.13	0.71	0.12	−0.13
Eigenvalues/Explained variance (%)	4.09/31.44%			4.29/32.98%			4.23/32.52%		
FACTOR 2: REGARD									
2. I respect my father's opinion.	−0.09	0.85	0.04	−0.05	0.89	0.29	−0.09	0.79	−0.07
5. I look forward to seeing my father.	−0.03	0.89	0.05	−0.16	0.88	0.20	0.04	0.84	−0.01
9. I know I can rely on my father to help me if I need him.	0.12	0.80	0.09	0.17	0.64	0.42	0.18	0.67	−0.01
12. I don't mind putting myself out for my father.	0.01	0.85	0.14	−0.01	0.89	0.41	0.07	0.85	0.02
Eigenvalues/Explained variance (%)	3.56/27.38%			3.53/27.15%			3.17/24.34%		
FACTOR 3: RESPONSIBILITY									
3. Something will happen to my father if I don't take care of him.	0.16	0.10	0.85	0.25	0.29	0.82	0.32	−0.01	0.69
6. I feel responsible for my father's happiness.	−0.04	0.77	0.47	0.10	0.62	0.49	−0.01	0.68	0.38
10. If I don't see my father for a week I feel guilty.	0.09	0.35	0.72	0.14	0.35	0.89	0.24	0.41	0.68
13. My father thinks I'm good in a crisis so he calls on me all the time.	0.19	0.08	0.64	0.31	0.32	0.72	0.29	0.14	0.78
Eigenvalues/Explained variance (%)	1.18/9.07%			1.22/9.38%			1.12/8.60%		

Value ≥ 0.50 are shown in bold.

**FIGURE 2 |** Plot of the first 13 eigenvalues on PACQ for mother.

in a Chinese cultural background. The results of the PACQ for mother indicated that the Model V fit the data significantly better than the Model IV [ $\Delta\chi^2_{(2)} = 666.85$ ,  $p < 0.001$ ;  $\Delta CFI = 0.074$  and  $\Delta TLI = 0.087$ ; Table ]. Meanwhile, the three-factor model with double loading fit the data considerably better than the three-factor model [ $\Delta\chi^2_{(2)} = 357.28$ ,  $p < 0.001$ ;  $\Delta CFI = 0.051$  and  $\Delta TLI = 0.049$ ]. Thus, the three-factor model with double loading was more suitable for analyzing mother and adult-child relationship results in a Chinese cultural background.

The loadings of each item on the corresponding latent construct of the PACQ for mothers and fathers of the three-factor model are reported in Tables , . All loadings for the items on the corresponding latent variables were statistically significant (all,  $p < 0.01$ ). Only one item with a potentially low loading ( $< 0.50$ ) was identified, which was from the PACQ for mothers of the attachment dimension item 5 ( $r = 0.40$ ). Although factor loading of this item was below 0.50, the signs of the loadings were in the correct direction. Moreover, the regard, responsibility, and attachment/control variables were correlated with each other (range,  $r = 0.11$ – $0.66$ ). The most significant positive correlation was between responsibility and regard ( $r = 0.66$ ,  $SE = 0.036$ ).

## Internal Consistency

Descriptive data for the Chinese version of the PACQ for fathers had Cronbach's  $\alpha$  coefficients of 0.88 for control, 0.88 for regard, and 0.68 for responsibility, and the PACQ for mothers had Cronbach's  $\alpha$  coefficients of 0.76 for attachment, 0.91 for regard, and 0.83 for responsibility (see Tables , ). The scales of the Chinese version thus maintained an internal consistency that was similar to that of the original English version of the PACQ (Peisah et al., 1999).

## The Effects of Age, Gender, and Education Level on the PACQ Results

We explored the effects of adult-child characteristics (age, gender, education level, *hukou*) on the relationship between adult-child and their parents. Dependent variables included three

**TABLE 4 |** Principal Factor analysis of the PACQ for mother.

Group 1 (n = 223)	Factor loading								
	All			Sons			Daughters		
FACTOR 1: REGARD									
1. I look forward to seeing my mother.	0.76	0.23	0.01	0.82	−0.02	−0.03	0.72	0.13	−0.04
4. My mother is my best friend.	0.79	0.14	0.21	0.86	0.01	0.07	0.75	−0.08	0.19
6. My mother shows her appreciation of me.	0.73	0.15	0.20	0.82	0.18	0.03	0.72	−0.12	0.16
9. I respect my mother's opinion.	0.89	0.17	−0.01	0.90	−0.09	0.03	0.88	−0.03	−0.12
12. I am glad to be able to repay my mother for all the love and care she gave me as a child.	0.80	0.27	0.02	0.88	0.03	0.03	0.76	0.16	−0.08
Eigenvalues/Explained variance (%)	4.43/34.09%			4.97/38.24%			4.32/33.23%		
FACTOR 2: RESPONSIBILITY									
2. I feel responsible for my mother's happiness.	0.24	0.81	0.14	−0.02	0.80	−0.02	0.02	0.79	0.11
3. I feel that I should take care of my mother because she has suffered so much in her life.	0.22	0.85	0.01	−0.03	0.89	−0.05	−0.06	0.83	−0.06
10. I feel that I have to protect my mother.	0.41	0.68	0.09	0.39	0.76	−0.03	0.33	0.65	0.04
Eigenvalues/Explained variance (%)	2.09/16.11%			2.40/18.48%			1.99/15.32%		
FACTOR 3: ATTACHMENT									
5. My mother's difficulty in making decisions has been a burden on me.	−0.33	0.08	0.58	−0.49	0.19	0.48	−0.40	0.05	0.63
7. I am the only one my mother can rely on.	0.06	0.11	0.57	−0.05	0.37	0.49	0.02	0.01	0.61
8. My mother thinks I am good in a crisis so she calls on me all the time.	0.16	0.13	0.58	0.11	0.16	0.66	0.10	0.08	0.54
11. My mother relies on me too much.	0.14	0.02	0.81	0.08	−0.15	0.94	0.11	0.04	0.77
13. I feel like I parent my mother.	0.14	−0.07	0.72	0.01	−0.18	0.78	0.19	−0.10	0.72
Eigenvalues/Explained variance (%)	1.08/7.84%			1.20/9.21%			1.00/7.44%		

Value  $\geq 0.50$  are shown in bold.

<b>PACQ FOR FATHER AND MOTHER</b>										
Model VI: hierarchical model	6590.18	299	22.04	—	—	0.553	0.514	—	—	0.215

n = 231 (group 2); CFA, confirmatory factor analysis; CFI, comparative fit index; TLI, Tucker-Lewis index; RMSEA, root mean square error of approximation;  $\chi^2/df$ , the associated p-values were always  $< 0.001$ .

Model I: PACQ for father original three-factor (control, regard, and responsibility) model.

Model II: PACQ for father original three-factor model, and separate item 6 from responsibility factor to regard factor.

Model III: PACQ for father original three-factor model, and freeing paths between the responsibility item 6 and the regard factor.

Model IV: PACQ for mother original two-factor (regard and responsibility) model.

Model V: PACQ for mother original three-factor (regard, responsibility, and attachment) model.

Model VI: a hierarchical model assuming the unidimensionality of the measure (i.e., PACQ for father original three-factor and PACQ for mother original two-factor).

\*\*\*p < 0.001.

dimensions of the PACQ. The results showed that adult-child characteristics were likely to affect the relationship between adult-child and their parents. The results were based on Pillai's trace. Looking at results for father and mother respectively, there were no significant main effects for fathers. For mothers, main effect was only significant in *hukou* ( $p < 0.05$ ). Based on

the univariate ANOVA, *hukou* also had a significant impact on responsibility [ $F_{(1, 223)} = 3.18$ ,  $p < 0.05$ , partial  $\eta^2 = 0.033$ ]. By looking at the mean values, an agricultural *hukou* was significantly associated with higher scores (agricultural vs. non-agricultural,  $(7.28 \pm 1.90)$  vs.  $(6.45 \pm 2.34)$ ,  $t = 3.96$ , Cohen's  $d = 0.40$ ).

**TABLE 6 |** Confirmatory factor analysis and factor correlations based on responses to the PACQ for father.

Revised three-factor model, Model fit results:  $\chi^2 = 358.32$ ,  $df = 62$ , comparative fit index (CFI) = 0.953; Tucker–Lewis Index (TLI) = 0.940; root mean square error of approximation (RMSEA) = 0.103.

PACQ for father: Control scale (item 1, 4, 7, 8, 11); Regard Scale (item 2, 5, 6, 9, 12); Responsibility Scale (item 3, 10, 13).

\* $p < 0.05$ , \*\* $p < 0.01$ .

## DISCUSSION

The present study developed the Chinese version of the PACQ for the first time and assessed its reliability and construct validity. We found that the Chinese version of the PACQ is reliable and suitable for the assessment of Chinese parents and their adult-children relationship. The original PACQ and the Chinese version of the PACQ both showed favorable psychometric properties in terms of reliability (Cronbach's  $\alpha$  was 0.74~0.87; Peisah et al., 1999, p. 32). In the present study, the Cronbach's  $\alpha$  coefficient of Chinese version PACQ for each dimension was acceptable (0.68~0.91). In addition, the dimensions of the Chinese version of the PACQ for fathers were regard, responsibility and control, which were similar to the original English version. However, for mothers, a new factor “attachment” was derived from the original English version.

The Chinese version of PACQ assesses three factors for father (responsibility, regard, and control), and it's also assesses three factors for mother (responsibility, regard, and attachment). Both Chinese father and mother are responsible for their children and with mutual respect. However, most Chinese fathers often take much more time on the work than family, while is very different with the father in Western culture who pay more attention on the interaction with children. A survey found that most Chinese fathers have little time with children, and that mothers tend to play as a leading factor in children's development (Wu et al.,

2017). This may lead to the relatively more attachment between children and mothers, than those with fathers (Bureau et al., 2017). Consequently the emerging factor “attachment,” which was derived from the original English version for mother, may be result from these factors.

Atkinson (1989) proposed the attachment theory that mother represents security and the typical source of a child's initial attachment and identification. Researchers found that the attachment was related with children's behavior and mental health (Bovenschen et al., 2016; Pallini et al., 2017). Insecure attachment between mother and children may be a risk factor in children's development (Cicchetti and Greenberg, 1991). Mother is the first significant attachment figure in a person's life (Bureau et al., 2017).

TABLE 7 | Confirmatory factor analysis and factor correlations based on responses to the PACQ for mother.

Item No.					CFA Standardized loading		
					Regard	Responsibility	Attachment
1. I look forward to seeing my mother.					0.82**		
4. My mother is my best friend.					0.81**		
6. My mother shows her appreciation of me.					0.78**		
9. I respect my mother's opinion.					0.88**		
12. I am glad to be able to repay my mother for all the love and care she gave me as a child.					0.84**		
2. I feel responsible for my mother's happiness.						0.85**	
3. I feel that I should take care of my mother because she has suffered so much in her life.						0.80**	
10. I feel that I have to protect my mother.						0.72**	
5. My mother's difficulty in making decisions has been a burden on me.							0.40**
7. I am the only one my mother can rely on.							0.57**
8. My mother thinks I am good in a crisis so she calls on me all the time.							0.68**
11. My mother relies on me too much.							0.80**
13. I feel like I parent my mother.							0.64**

Dimensions					Correlation between latent variables		
					Regard	Responsibility	Attachment
Regard	5	10.86	3.61	0.91	1.00		
Responsibility	3	7.02	2.08	0.83	0.66**	1.00	
Attachment	5	5.82	3.10	0.76	0.34**	0.29**	1.00

Three-factor model, Model fit results:  $\chi^2 = 597.16$ ,  $df = 62$ , comparative fit index (CFI) = 0.941; Tucker-Lewis Index (TLI) = 0.925; root mean square error of approximation (RMSEA) = 0.138  
PACQ for mother: Regard Scale (item 1, 4, 6, 9, 12); Responsibility Scale (item 2, 3, 10); attachment scale (item 5, 7, 8, 11, 13).

to attachment and care. This result suggests that, as well as concerning about their fathers' happiness consistent with that in Western culture, Chinese adult-children also feel the duty of providing with more care for their fathers. Huff (2015) found that "for my father's happiness" may be particularly linked to REN (仁, meaning Mercy, Gentle, Kindness, loving, Caring) that is highlighted by Mencius theory (Man is naturally good) as a priori for Chinese people's personal accomplishment.

The study firstly developed the Chinese version of the PACQ and explored the present (adult-child) relationship in urban and rural areas in China. We found agricultural *hukou* was significantly associated with mother's responsibility. This may result from the fact that China's rural insurance system for older people started late and was still incomplete (Holroyd, 2003; Rokicki and Donato, 2016). Thus, rural adult-children are more responsible for raising parents. Compared with the original English version, the Chinese version of the PACQ showed better validity and similar reliability coefficients, which indicated the Chinese version of the PACQ is suitable for assessing Chinese parent adult-child relationships. In addition, a new factor "attachment" was derived from the original English version, which indicated the relationship between mother and their adult-child were close with each other.

The study has some limitations. Firstly, the present sample was from Anhui province only, future studies should therefore recruit participants from other provinces in China. Secondly, we did not test convergent validity in this study, and future studies should to verify the external validity of the Chinese version of the PACQ. Finally, we recommend that future versions of the PACQ consider testing different items for the scales to improve the variety, specifically, measurement invariance across Chinese and Western cultures in adult
